

## How To Think Recursively

- ① What are recursive functions?  
→ A function which is defined itself
- ② Why are they useful?  
→ Most functions naturally are recursive in Haskell
- ③ Why are they difficult at first?  
→ Switching over from imperative, loop based programming

## 7 Step Process for Recursion functions

- ① Name the function.
  - ② Write down it's type.
  - ③ Enumerate the cases.
  - ④ Define the simple cases.
  - ⑤ List the "ingredients".
  - ⑥ Define the other cases.
  - ⑦ Think about the result.
- ↓  
Helper for writing the functions

Problem: Define a function that calculates the sum of a list of numbers → Any numeric type

①  $\text{sum} :: \text{Num } a \Rightarrow [a] \rightarrow a$   
② & ⑦  
③  $\text{sum} [] = 0$  ④  
③  $\text{sum } (x:xs) = x + \text{sum } xs$  ⑥

⑦ can it be generalized the type and simplify the cases

⑦  $\text{sum} = \text{foldr } (+) 0$

Problem: Define a function that drops a given number of elements from the start of a list.

$\text{drop} :: \text{Int} \rightarrow [a] \rightarrow [a]$

$\text{drop } 0 \text{ []} = []$

$\text{drop } 0 (x:xs) = x:xs$  }  $\rightarrow$  The original list is unchanged

$\text{drop } n \text{ []} = []$

$\text{drop } n (x:xs) = \text{drop } (n-1) xs$

$\rightarrow$  can get rid of this

$\rightarrow \text{drop } 0 \text{ xs} = xs$

$\rightarrow \text{drop } - \text{ []} = []$

$\rightarrow \text{drop } n (-:xs) = \text{drop } (n-1) xs$
